

**REMARKS**

***Formal Matters***

Applicant thanks the Examiner for acknowledging the claim for foreign priority and receipt of the priority documents.

Claims 1-18 are all the claims pending in the application. Claim 1 is the only independent claim. Claims 2-4 and 18 have been withdrawn from consideration, as being directed to a non-elected invention. Claims 1 and 5-17 have been examined.

***Drawings***

The Examiner has objected to the drawings. First, the Examiner alleges several inconsistencies between the drawings and the specification. In view of this objection, Applicants have amended the drawings by deleting reference numerals not mentioned in the specification and also providing the alternative reference numerals 26A', 26B', 43', and 43''. The proposed amended drawings are attached.

Second, the Examiner alleges that some features from the original claims are not shown in the drawings. As is discussed below, Applicants have cancelled original claims 1-18 and have added new claims 19-34. Applicants respectfully submit that in view of canceling the original claims and adding the new claims, this objection is moot.

Finally, Applicants have also provided new Figures 28 and 29 in order to overcome the Examiner's objection to the drawings with respect to original claim 6.

New Fig. 28 is not new matter at least because it is supported by page 13, lines 23-27 (now labeled para. [0058]) of the original specification. Fig. 28 represents an *additional non-limiting* embodiment of claim 6 (new claim 22) and is a modification of Fig. 27.

In Fig. 28, the central hydraulic device (43') has been separated into two simple central devices (73) which are equal and result from division into two halves of said central hydraulic device (43') of figures 22, 23 and 24, which can be considered as double, each simple device comprising the double piston (55), formed by the pistons of larger (55A) and smaller (55B) diameter which reciprocate, respectively, in cavities (56'-57' and 58'-59') of each of the cylinders (52'-53').

In this spatial configuration of the simple central hydraulic devices (73) the end cavities (74), formed between the larger diameter pistons (55A) and the closed wall of the cavities (56'-57') are connected by means of conduit (75) which interposes a three way valve arrangement (76), flanked by two pneumatic expansion chambers (62'), allowing that acting on the pistons of larger diameter (55A) of both simple central hydraulic devices (73), provided with hydropneumatic damping means (67'), increases the height of the body of the means of the conduits (61) with the cavities (56'-57' and 58'-59') of the cylinders (52'-53') constitutive of the simple central hydraulic devices (73).

In addition, Applicants have added new Fig. 29, which is a combination of Figs. 27 and 28.

With respect to the objection to claim 10 (new claim 26), Fig. 22 shows a *non-limiting* embodiment of the damping means (67) inserted in the conduits (61).

With respect to the objection to claim 11 (new claim 27), Fig. 26 shows a *non-limiting* embodiment of conduit (61) in which the expansion chambers (68) are inserted through electro-valves (69), such as described in lines 6-12 on page 14.

With respect to the objection to claim 14 (new claim 29), a *non-limiting* embodiment of the feature of a means for introducing pressurized gas is shown in, for example, Figs. 21, 23 and 24 and described in the specification at page 14, lines 22-31. Reference numerals have been added for the entries (M) of a fluid pressurized by a pump in Figs. 21, 23, and 24 and for the pump (P) in Fig. 21.

With respect to the objection to claim 16 (new claim 31), as non-limiting embodiment of flow from one cavity to another is now shown in new Fig. 29. This feature has been described in the original specification at page 14, lines 8-32 and page 15, lines 1-4.

### ***Specification***

The Examiner has objected to the specification, alleging several informalities. In response, Applicants are submitting a substitute specification -- two versions of the substitute specification, one showing changes and one with the changes made.

### ***Claim Objections and Rejections under 35 U.S.C. § 112***

The Examiner has made several objections and rejections under 35 U.S.C. §112, first and second paragraphs. As is discussed below, original claims 1-18 have been cancelled and new claims 19-33 have been added. Applicants respectfully submit that these objections and rejections are moot in view of the cancellation of the original claims.

In view of the multitude of rejections, Applicants have cancelled original independent claim 1 and added new independent claim 19, as shown hereinabove.

In addition, Applicants have added new dependent claims 20-33, which correspond to original claims 2 and 5-12, and 14-18, respectively. Applicants respectfully submit that the new claims except new claims 2 and 33 are directed to the elected species.

***Claim Rejections Under 35 U.S.C. § 102 and §103***

Claim 1 is rejected under 35 U.S.C. § 103(a) as being allegedly anticipated by Rhodenburg (DE 28 10 629). Claims 1, 5, and 6 are rejected under 35 U.S.C. § 102(e) as being allegedly anticipated by Heyring et al. (US 6,270,098). Claims 1, 5-7, 10, 13, and 14 are rejected under 35 U.S.C. § 103(a) as being allegedly unpatentable over Sakai (US 5,486,018) in view of Heyring and Rhodenburg.

With respect to new independent claim 19, Applicants respectfully submit that the claim is allowable at least because none of the applied references teaches or suggests the claimed device having a central resilient element, and two central actuating elements, wherein the central resilient element is capable of opposing a force provided by a first of the central actuating element and a force provided by a second of the central actuating elements.

For example, Rhodenburg discloses a flow distributor having pistons and cavities, but does not disclose a central resilient element with two central actuating elements. Rhodenburg at Figs. 1-3. In addition, Heyring discloses a vehicle with a central load distribution system including fluid chambers with rods 34, 35 that expel fluid out to fluid communicating conduits

14, 14, 16, 17 when fluid is communicated into the distribution system by the fluid communicating conduits.

However, Heyring is deficient at least because Heyring's central load distribution system is not capable of transmitting a force via a wheel transforming element to a wheel actuating element associated with a set of at least one wheel that is diagonally opposed to a set of at least one wheel that is subjected to a vertical force. Instead, the rods 34,35 merely transmit a force to adjacent wheels. For example, Fig. 1 shows that the force of the hydraulic ram 2 is directly transmitted to the diagonally opposed hydraulic ram 1 by the conduit 10.

Finally, Sakai discloses a suspension system having at least one pressure balance control accumulator arrangement 115 including an accumulator and a flow control 114. *See Sakai at Figs. 1-14.* However, Sakai does not disclose the claimed invention. For example, Sakai merely shows in Fig. 10 an embodiment in which the diagonally opposed shock chambers 102 are connected by separate accumulator arrangements 116. Furthermore, Fig. 12 of Sakai shows a accumulator that connects the shock chambers 102 to adjacent shock chambers. The opposing shock chambers 102 are instead directly connected.

Applicants respectfully submit that no combination of the applied references would include all of the limitations of new claim 19.

Therefore, for the reasons discussed above, Applicants respectfully request the Examiner to allow new claim 19. In addition, Applicants request the Examiner to allow dependent claims 20-33 at least because of their dependency from claim 19.

Amendment Under 37 C.F.R. § 1.111  
Serial No. 10/031,872

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

ANTIROLL AND ANTI-PITCH SYSTEM FOR A VEHICLE, AND  
DEVICE FOR ITS IMPLEMENTATION

DESCRIPTION

Field of the invention

[0001] This invention relates to an antiroll and anti-pitch system for a vehicle, and to the devices for its implementation, specifically a system to be applied to vehicles provided with four sets of one or more wheels~~wheeling sets, specially four of them. , each~~The system constituted by one or more wheels, such system that cooperating either cooperates with the vehicle's suspension system or substituting it~~substitutes for the vehicle's suspension system, allows that the wheeling sets in order to allow the four sets of wheels to keep contact with the ground and to keep an even distribution of load even in the case of if the vehicle is subject to uneven terrain. , being such wheeling sets~~ Where the sets of wheels are provided in a two-by-two manner, the sets that diagonally oppose each other are related~~related two to two in diagonal direction~~, in such a way that the loads created by the vertical movements of one of the ~~wheeling sets~~ are transmitted to the opposite ~~wheeling set set~~ in order to transmit such a force that creates a similar movement in the vertical direction of ~~such wheeling set~~ the opposite wheel. , so as thatThe system cooperates cooperating with the suspension of the vehicle, or substituting it is substituted for the suspension of the vehicle, in order to allow that all of the vehicle's wheels to keep contact with the ground even if the terrain it is irregular and do not induce prevents unwanted effects on that are caused by the an uneven terrain.

[0002] ~~A Vehicle~~vehicle suspension is built mainly with coil springs and resilient elements that bear the vehicle body, transmitting and transmit its weight and the inertial forces to the ~~wheeling sets~~wheels. , providing theThis provides a means to absorb the shakes vibrations caused by the travel of the vehicle over the road irregularities. Such springs and elastic elements are accompanied with shock absorbers in order to ~~model~~minimize the sprung movements and to avoid prolonged oscillations.

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

[0003] In addition to absorbing vibrations or shocks from the road surface, a vehicle suspension must provide ~~security of a~~ a safe ride, keeping an optimal position in the straight trajectory, and vehicle ~~security~~ safety during cornering.

[0004] Vehicle stability is strongly related with the oscillations of the vehicle body along its course, ~~or when it~~ the vehicle experiences ~~roll, heading, and spin~~ pitch, and roll movements in addition to rebounds. Such oscillations have to be absorbed to ~~increment~~ increase the stability and comfort of vehicle ride.

State of the art

[0005] Stabilizing bars are well-known means used to control the roll naturally generated when the ~~a~~ vehicle is in operation.

[0006] ~~A Conventional~~ conventional anti-roll system uses a stabilizing bar that has a small resilient component to ~~get the~~ provide adequate comfort ~~along during the ride, but then it~~ This system, however, cannot accomplish its purpose satisfactorily when the vehicle turns, ~~being this caused by~~ due to the centrifugal force generated when cornering.

[0007] On the contrary, if the anti-roll bar is very stiff, it will interfere with the suspension system and will ~~deteriorate~~ impair the comfort of the vehicle ride.

[0008] ~~We have knowledge of existing~~ In U.S. patents ~~2,840,387~~ 2,840,387 ~~in which,~~ the forces created in a vehicle wheel as it turns are transmitted by two tie-rods to the diagonally opposed wheel, which reproduces the force in the same direction, 3,147,990. ~~In US patent 3,147,990, in which the wheels on one side of the vehicle are connected to each other and also to those on the other on the other side by means of torque arms. In, 3,992,026~~ U.S. patent 3,992,026, where right and left torsion bars that generally extend in the longitudinal direction, and interconnect the right and left sides of existing a front anti-roll bar with right and left rear suspension arms,

respectively, ~~In 5,505,479~~ U.S. patent 5,505,479, ~~where~~ two front suspension lower arms ~~transversally~~ are aligned transversally between opposite front and rear wheels, and ~~related between them~~ connected by a resilient element located longitudinally, ~~all this with for~~ the purpose of transforming the vertical movements of the wheels into a rotary motion as seen from the front of the vehicle, ~~and U.S. 5,882,017~~ patent 5,882,017, ~~where~~ a perpendicular connecting rod is coupled to the vehicle and a pair of articulating elements ~~that~~ link such connecting rod to the front wheels, including a pair of travel limits selectively actuated that communicate with the central part of such connecting rod.

[0009] ~~We also have knowledge of patents~~ In ES 2110 509, ~~in which~~ the forces created in one wheel are transmitted hydraulically to the diagonally opposed wheel, using double-effect hydraulic cylinders. In, WO 95/23076, ~~in which~~ similar to the above, the forces created in one wheel are transmitted to the diagonally opposed wheel by means of double-effect cylinders and, in one case, the single-effect cylinders connect the wheels on one side to each other and to a central device, In FR 1.535.641. US ~~3,752,497~~ patent 3,752,497 and US patent 5,447,332, ~~where~~ double acting hydraulic rams are used on each wheel ~~related~~ provided ~~two to two~~ two-by-two, ~~having the~~ The last two patents having a central device that relates the four wheels and includes a double or triple hydraulic cylinder where some linked pistons move in the same direction.

Summary of the invention

[0010] All known anti-roll systems interfere ~~at certain to some~~ extent with the existing suspension system, as they have to show a critical resiliency to suit stability and adaptability to uneven terrains.

[0011] Therefore, it is desired to have an anti-roll system, and also an anti-pitch system that would not interfere in geometric terms with the existing suspension system, and that can

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

cooperate with the suspension system or substitute ~~it~~ for the suspension system, being able to show an arbitrary rigidity without compromising the vehicle stability.

[0012] With such premises, ~~it has been developed the~~ an anti-roll and anti-heading system for a vehicle has been developed that, along with its implementation devices, ~~constitutes~~ provides the object of present invention. ~~consisting this~~ In this system ~~in the arrangement between the wheeling sets~~ wheels are related through interaction means that receive the effect from one or more ~~wheeling set wheels~~ wheels and ~~adequate them~~ before transmitting the effect ~~it~~ to the other ~~wheeling sets~~ wheels in order to maintain a uniform load distribution of the weight and reduce the vehicle heading and rolling.

[0013] The invention assumes that the ~~transmission of the~~ forces created by the vertical movements from one ~~wheeling set~~ of wheels are transmitted to the diagonally opposite ~~one~~ onset of wheels ~~implemented either~~ through mechanical means able to resiliently resist forces of traction, compression, torsion and flexion, through hydraulic means, through pneumatic means or through electrical or electronic means used to command servo actuators on each wheel. ~~being these~~ These means can be considered provided either separately or any combination ~~of their combinations~~.

[0014] According to the above-mentioned possibilities of implementing the system, the invention includes several cases of proper devices to implement the current system.

[0015] As in this invention, an anti-roll and anti-pitch device for a vehicle comprises a receiving element ~~that associated~~ connected with a first ~~wheeling set~~ of wheels of the vehicle, which transmits the wheel vertical movements to a direct transforming element that converts ~~them~~ the vertical movements into horizontal movements. ~~which in turn, through an~~ An inverse transforming element converts these horizontal movements ~~are converted~~ into vertical movements that ~~take effect onto a~~ are transmitted to a second wheeling set diagonally opposed to

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

the first wheel, causing a vertical movement analogous to the ~~one in~~ movement of the first ~~wheeling set~~ wheel.

[0016] In all these cases, the direct transforming element is related with the inverse transforming element by means of a transmission element that can be mechanical, hydraulic, pneumatic or electric.

[0017] One characteristic of this invention is the case where receiving and actuating elements are made of a rod connected on one end to one wheeling set through a universal joint, while the other end is articulated to a direct transforming element in the receiving end case, and to an inverse transforming element in the case of an actuating element. In this case, the direct transforming element is a first kind angled connecting rod, and the inverse transforming element is a second or third kind angled connecting rod, which pivot points are supported by the vehicle body through bearings.

[0018] According to this invention, the transmission means between pairs of direct and inverse transforming elements are made up by a rigid bar, connected at its ends with each transforming element. It has been anticipated too that the transmission means can be made of two flexible stays, in which case the two transforming elements are made of three arms connecting rods shaped as "T", with the pivot point near the intersection, the stays connected to the two ends of the shorter arms, and the third arm of both transforming elements working in the vertical direction.

[0019] It is also a characteristic of this invention that the resilient elements connected to the transmission elements are connected to the ~~the~~ vehicle body through an articulated balance beam, in such a way that the its ends are connected to the resilient elements and the center is joined to the vehicle body.

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

[0020] Another characteristic of this invention is that the receiving and actuating elements can be the rods of pistons of single effect hydraulic rams, which are in turn the direct and inverse transforming elements, related through hydraulic conduits.

[0021] In one case, the hydraulic circuit is constituted by the two single effect hydraulic cylinders, which are the direct, and inverse transforming elements, and a hydraulic conduit that includes an inserted actuating device to keep the pressure in the circuit.

[0022] It is also a characteristic of this invention that when each receiving and actuating device is made up of single effect rams, the direct and inverse transforming elements are organized through interaction means made up of a central device built as a hydraulic ram containing two opposed concentric pistons with same areas each, and a spring or pressurized fluid acting in between of them, having each cylinder end a coaxial cylindrical compartment in correspondence with the active sections of such pistons, having each compartment a connection with the respective receiving or actuating element.

[0023] There is another preferred implementation where the interaction means that are related with each pair of ~~wheeling-sets~~ of wheels is built as a central hydraulic device made of three concentric coupled cylinders, closed at the ends of the set, where the central cylinder is of a larger diameter, and the two cylinders at its sides are both of equal diameter, having inside the cylinders two double-pistons, with no external rod, and one larger piston found inside the central cylinder, and a smaller piston in one of the smaller cylinders, in such a way as to determine five cavities: one central cavity, and two pairs of cavities at each side of the device separated by the smaller diameter pistons, being the double cavities at each end of the device connected respectively to the hydraulic conduits corresponding to hydraulic single effect rams at each diagonally opposed wheeling set, while the central cavity is connected to an actuating device built with resilient means and/or a fluid susceptible of being connected to an expansion chamber that opposes to the two double pistons getting closer to each other.

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

---

[0024] Another characteristic of the invention is that the central device central cylinder has an area approximately double to the areas of each side cylinder.

[0025] It is evident that with the ~~appropriate~~appropriate modifications, such hydraulic elements can be adapted to become of pneumatic type.

[0026] The invention anticipates that the resilient means in the central cavity are actually provided by two elastic elements, each actuating independently on each of the larger pistons that close such central cavity, so the central hydraulic device is divided in two halves related through an additional conduit provided of flow regulation means.

[0027] Each double piston in the central hydraulic device can be built from two or more conventional pistons, linked with each other although actuating each one on independent hydraulic single effect rams, in such a way that the two or more new cavities of the new cylinders come to substitute the two pairs of cavities formerly separated by each piston of smaller diameter following the diagonal scheme, and linking the two groups of pistons through a resilient element acting as the former central cavity.

[0028] The invention contemplates the following facts:

a) Hydraulic fluid regulation or damping devices are inserted in the hydraulic conduits from the central device to each hydraulic ram linked to the wheeling sets, or in between the cylinders associated to conjugated wheeling sets.

b) The central cavity, the two pairs of side cavities, the conduits that connect these with the hydraulic rams at each wheeling set, or the hydraulic cylinders can be connected to one or more expansion pneumatic chambers through electro valves.

c) The four conduits that connect the double side cavities from the central hydraulic device to each hydraulic ram at the wheeling sets is susceptible of being communicated through

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

devices that allow a limited volume flow depending on the pressure differential between the conduits, being these devices preferably applied between conduits to wheeling sets at the same side of the vehicle.

[0029] It is also possible to provide the means of introducing pressurized hydraulic or gaseous fluid in the central cavity, or drain it, with the purpose of varying the average distance between the wheels and the vehicle body. For this purpose it can also be used a mechanical device to provide a thrust between the two larger diameter pistons found in the central cavity of the central hydraulic device.

Brief description of the drawings

[0030] FIG. 1 is a diagrammatic representation of the anti-roll and anti-pitch suspension system for a vehicle.

Detailed description

[0031] The proposed anti-roll and anti-pitch suspension system relates, as represented in FIG 1, the pairs of diagonally opposed vehicle wheels, in such a way that the forces created by the vertical movements of one of them are transmitted to the conjugated wheel in order to communicate a force that determines analogous movements in the same vertical direction.

[0032] FIG 1 shows the front-left wheel A, front-right wheel B, rear-left wheel C and rear-right wheel D. The proposed system relates wheels A with D, and wheels B with ~~D~~C.

[0033] The axis of each wheel A, B, C and D is linked with a rigid element 1, which in turn is connected on wheels A and B to first kind connecting rods pivoting on 3, and on the other wheels to second or third connecting rod 4 pivoting on 5, being each connecting rod 2 related with connecting rod 4 diagonally opposite through a transmission element 6.

[0034] FIG. 2 shows how a vertical force FB created by the terrain irregularities on the element 1 of wheel B is transformed through the corresponding connecting rod 2 into a non vertical force F

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

that goes to the corresponding connecting rod 4 and gets transformed into a vertical force FC analogous to FB in direction and intensity.

[0035] The transmission of forces determined by the vertical movements in any of the two wheels of a diagonally opposed set is carried through mechanical means able to resiliently resist traction, compression, torsion and flexion forces, hydraulic and/or pneumatic means, and electric and/or electronic means that actuate through actuators on each wheel.

[0036] In general, this system can be implemented through a device as described below following again FIG 2.

[0037] The device has a rigid element 1 that related with a first vehicle wheel B transmits its vertical movements FB to a direct transforming element such as connecting rod 2 that transforms them into horizontal or non-vertical movements, which in turn are transmitted through the elements 6 into an inverse transforming element such as connecting rod 4 that transforms these horizontal movements into vertical movements of the rigid actuating element 1 of a diagonally opposite second wheel C, subject then to a vertical movement analogous to the first wheel.

[0038] We have named receiving element or actuating element to the same rigid element 1, using the first meaning when this is the element that receives the terrain irregularity, and the second meaning when it actually transmits the movement to the wheel, so on both wheels receiving and actuating elements are the same. Analogously we can apply the same convention to the inverse and direct transforming elements.

[0039] In one of the implementations of this device, the rigid elements 1 acting as receiving or actuating element, are made up by an articulated connecting rod, linked through a joint 7 to one wheel at one end, and through a second joint 7 to a direct transforming element in the other end, being this transforming element made of a first kind angled connecting rod 2 when the rigid

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

---

element 1 works as a receiver, and an inverse transforming element made of a second or third kind angled connecting rod 4 when the rigid element 1 works as an actuator.

[0040] The transmission means 6 are made up by: a rigid bar linked at each end to the transforming elements 2 and 4 as seen in FIG 1 and 2; a one-piece torsion bar 8 linked to the vehicle body at point 9 such as in FIG 3; by a torsion bar articulated through universal joints 10 as in FIG 4; and by two flexible pull-rods 11 as in FIG 5, where the two transforming elements are made of "T" shaped connecting rods 12 of three arms pivoting on 3 near the intersection, being the ends of the aligned arms connected to through joints 7 the ends of the crossing pull-rods 11, in such a way that the third arm actuates along the same vertical direction at each rigid element 1 working as receiving or actuating elements.

[0041] Another implementation of the invented device, as seen in figure 6, the rigid elements are the rods 13 connected to the pistons 14 of single effect hydraulic rams 15 mounted through a joint 15A to the vehicle body, being such pistons the direct and inverse transforming elements as shown in FIG 6, where the hydraulic rams 15 are related through conduits 16 that have an actuating device 17 that using hydraulic rams 18, elastic elements 19 and/or pneumatic means 20 keep the pressure in the circuit.

[0042] FIG 7 represents the case where each wheel has a conjugated pair of a servo actuator 21 related to a control unit 22.

[0043] As seen in FIG 8, direct and inverse transforming elements are made of torsion bars 23 with an arm 24 at each end; one connected to one wheel support 25, and the other to a transmission element 26. Such transmission elements 26 cross over in order to diagonally relate each conjugated pair of wheels.

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Appln. No. 10/031,872

Docket No. Q68112

[0044] As seen in FIG 9 and detail FIG 10, each transmission element 26A, 26 B is connoted to the vehicle body through an elastic element such as a coil spring 27 placed between two brackets, one 28 fixed to the vehicle, and the other 29 fixed to the end of the transmission element.

[0045] The placement of coil springs 27 can be implemented as indicated in FIG 11 and 12, where the transmission elements 33 are made of two segments 26A and 26B joined at a plate 30 attached to a coil spring 27. Such spring is mounted between two brackets 28 and 29, the ~~laterformer~~ fixed to a crossbeam 31 mounted on the vehicle body, having two rods 32 as a guide for the coil springs 27 and pushing ends 33 applied to the plates 30 that pass loosely through.

[0046] FIG 13 shows a configuration where the two coil springs 27 linked to the transforming elements 26 are related with the vehicle body through the balance beam 34, linked to the vehicle body through an axis going through the pivot point 35, and to the rods 32 at its ends, having like the previous case pushing ends 33.

[0047] FIG 14 shows a different configuration for balance beam 34 that has the brackets 28 and 29 at the ends of its arms with coil springs acting under compression like in FIG 9.

[0048] FIG 15, as in previous figures, shows the layout of the transforming elements 23 with a single compressing spring coil 27 that links the two crossing transmission elements 26 arranged in two parallel planes.

[0049] FIG 16 shows a layout where the direct and inverse transforming axis are arranged longitudinally in respect to the vehicle, and the transmission elements 26 are crossed in the transverse direction, having one single coil spring 27.

[0050] FIG 17 is a representation of a mechanical layout similar to FIG 15 where the transmission elements 26A and 26B are arranged on the same plane, side by side through the

---

single coil spring 27 mounted between the brackets 37, each of them joined to fixtures 38 and 39 each linked to one transmission element 26A and 26B as shown in the detail view 19

[0051] As it can be seen in figures 18 and 20, the transmission elements 26A and 26B are crossed over by means of the connecting arms ~~23~~24A-24D, so the arm 24B is related to arm 24C, and arm 24A to arm 24D.

[0052] In this invention, the elastic elements connected to the vehicle body can be mounted on one or two mechanic, electro mechanic or hydraulic actuating elements such that their movement in respect to the vehicle body varies its height in respect to the ground; the balance beam axis can be mounted on one or two mechanic, electro mechanic or hydraulic actuating elements such that their movement in respect to the vehicle body varies its height in respect to the ground; and the central resilient element can have a mechanic, electro mechanic or hydraulic actuating element able to move one of the resilient element fixtures, in such a way that varies its effective length, and by so varies the height of the vehicle in respect to the ground.

[0053] FIG 21 shows a variation where each receiving and actuating element of the two pairs of vehicle wheels is made up by the rods 40 of pistons 41 of single effect hydraulic rams 42, the direct and inverse transforming elements are arranged in a unique central hydraulic cylinder 43 containing two free moving and opposed pistons 44. ~~showing active~~Active areas 45 are equal and concentric, and are subject to an internal actuator made of a coil spring 46 and/or pressurized fluid 47, ~~showing each piston~~ On the outer side of each piston, a cylindrical and coaxial compartment 49 and a coaxial compartment 50 ~~that correspond to the active sections of such each piston-pistons, being~~ Each compartment 49 and 50 communicates with a connection 51 that extends towards the corresponding receiving and actuating element 40 for each of the diagonally opposed wheels.

---

[0054] In the above implementation, the active central section of free-moving pistons 44 can be eliminated, acting as active area the inner face where the coil spring is applied.

[0055] The actuating devices can be made up with a pair of single effect hydraulic rams as in FIG 6, with a common acting force. Such two cylinders can be concentric and of equal active area, be made up from three cylinders where one is equivalent to the other two, or four equal rams arranged at the ends of a cross.

[0056] FIGs 22 and 23 represent a variation where the central hydraulic cylinder 43 is made up joining three hollow concentric cylinders, with a central cylinder ~~57~~52 has a larger diameter, and the side cylinders 53 are the two equal and of smaller diameter, closed at their free ends 54. Inside such hollow body there are two free moving double pistons 55 made up one larger diameter piston 55A placed inside the larger central cylinder 52, and a smaller piston 55B placed inside the corresponding end cylinder 53, thus determining one larger central cavity 56 associated to the central cylinder, 52, two smaller intermediate cavities 57 and 58, and two smaller ending cavities 59 and 60 associated to the side cylinders 53, all cavities connected in such a way that the smaller intermediate cavities 57 and 58 are respectively communicated with the simple effect hydraulic ram 42 for wheels B and A, while the smaller end cavities 59 and 60 are respectively communicated with the simple effect hydraulic ram 42 for wheels C and D, ~~and the~~. The central cavity 56 has an actuating device made of resilient means such as pressurized fluid 62, coil spring 46 or rubber-like body, the two last cases not represented in ~~the figure~~ Figs. 22. One preferable implementation of such central hydraulic device 43' is shown in figures 23 and 24.

[0057] Preferably, the area of the central cylinder 52 is approximately double the area of each side cylinders 53.

Docket No. Q68112

[0058] The resilient means used in the actuator in the central cavity can be made of a double resilient element that independently pushes pistons 55A that close such larger central cavity 56. Another possibility is to divide the central hydraulic device 43' in two halves that ~~can be related~~communicate through an additional conduit that has means to regulate the flow of the fluid. This is shown in Fig. 28.

[0059] FIG 25 shows an arrangement of the central hydraulic cylinder 43'', where each double piston 55 is made of two or more related pistons 63 in single effect hydraulic independent rams 64. ~~with the purpose of~~The purpose of two or more cavities of these new cylinders can substitute the two intermediate smaller cavities 57 and 58 and end cavities 59 and 60 that are separated by the smaller diameter pistons 55B shown in FIG. 24. ~~being all~~The hydraulic conduits 61 are connected following the exposed in a diagonal arrangement, and relating are communicated all by the rods 65 of the two groups of pistons 63 through a single resilient element 66 acting as the actuating device used in the larger central cavity 5666.

[0060] FIG 22 shows how two-way regulation or damping devices 67 are inserted in the pipes and connect ~~connecting~~ the central hydraulic device with all simple effect hydraulic cylinders 42 associated with the wheels. Additionally, the larger central cavity 56, the smaller intermediate cavities 57 and 58, the end cavities 59 and 60, the hydraulic conduits 61 that connect ~~these~~the cavities with the hydraulic rams 42 associated to each wheel and the very hydraulic rams 42 are connected to the damping devices 67, which can be one or several pneumatic expansion chambers 68 that can be disconnected through electro valves 69, such as these represented in FIG. 26.

[0061] On the other side, the four main hydraulic conduits 61 that connect the smaller cavities 57, 58, 59 and 60 of the central hydraulic device 43' with the simple effect hydraulic rams 42 associated to the wheels are susceptible to be connected among them through devices that allow the flowing of a limited quantity of fluid depending on the pressure differential between the

SUBSTITUTE SPECIFICATION- CHANGES SHOWN

Docket No. Q68112

hydraulic conduits. This communication is preferably applied between hydraulic conduits from wheels of the same side of the vehicle. FIG 27 shows this device made up with a free-moving piston 70 between two coil springs 71 inside cylinder 71. Fig. 29 shows an arrangement including this communication.

[0062] It has also been anticipated having means to provide pressurized hydraulic or gaseous fluid or drain it from the larger central cavity 56 with the purpose of varying the average distance between the vehicle body and the wheels. The same result is obtained including a mechanical device that pushes the two larger diameter pistons 55A placed in the central cavity 56 in the central hydraulic device 43.

[0063] Therefore cavity 56 can include one or various resilient elements that have one or various mechanical, hydraulically or electromechanical actuators that can vary the average distance between the vehicle body and the ground.

[0064] Additionally it has been anticipated that each hydraulic conduit 61 is derived into one or more devices with a variable volume cavity such as that the circuit pressure increases, it compresses a resilient or pneumatic element that facilitates the entry of hydraulic liquid in the cavity. Analogously, each hydraulic conduit can have one or more regulating devices or valves, passive or active for the hydraulic fluid.

[0065] This invention anticipates that one or more wheels are substituted by sets of wheels, each wheel has one single effect hydraulic ram, and all rams communicated among them and with the hydraulic conduit of the wheel set corresponding to the central hydraulic device. Such substitution can be applied to a caterpillar device.

[0066] The invention also contemplates the fact that when the wheeling sets are made up of more than one wheel, each with the corresponding single-effect hydraulic ram, all the hydraulic rams

Appln. No. 10/031,872

Docket No. Q68112

ABSTRACT

~~This antiroll and anti-pitch system for a vehicle, and the device for its implementation that cooperates the vehicle suspension or substituting it, allows that the wheeling sets keep contact with the ground and a uniform load distribution even when the case of an irregular terrain, being such wheeling sets related two to two in a diagonal arrangement through interaction means that receive the thrust of one or more wheeling sets and adapt them to transmit them to the other wheeling set, with the purpose of maintaining the uniform load distribution and reduce the roll and heading of the vehicle.~~

~~The vertical forces detected in the wheeling sets work through mechanic, hydraulic, or electrical means made up by mechanic resilient elements, hydraulic and/or pneumatic elements and electronic devices.~~

An antiroll and anti-pitch device for a vehicle having four sets of at least one wheel provided in a two-by-two arrangement, including a central resilient element, two central actuating elements, four wheel actuating elements, and four wheel transforming elements. Each of the wheel actuating elements is associated with one of the four sets of at least one wheel and capable of providing a transmitting force determined by a vertical force to which the associated set of at least one wheel is subjected. The central resilient element is capable of opposing a force provided by a first of the central actuating element and a force provided by a second of the central actuating elements.
